

New Wheels — SQL Business Analytics

SQL / Data Analytics · Adewale Adeyinka Falade · joins, window functions, CASE, date math

Business Question

New-Wheels, a vehicle-resale company, saw orders and customer ratings decline quarter on quarter. The goal: a SQL-driven quarterly report to pinpoint where the business was losing ground — customers, brands, feedback, revenue and fulfilment.

Quarterly Trend (the core story)

Quarter	Orders	Net revenue	Positive feedback	Avg ship days
Q1	310	\$39.4M	~59%	57
Q2	262	\$32.7M	~51%	71
Q3	229	\$29.2M	~38%	118
Q4	199	\$23.3M	~20%	174

Key Findings

- Customer base is concentrated — California (97), Florida (86), DC (35) lead; many states under 10.
- Brand preference is fragmented — Chevrolet (83), Ford (63), Toyota (52); no national leader.
- Satisfaction collapsed — positive feedback fell from ~59% (Q1) to ~20% (Q4).
- Orders fell ~36% and net revenue ~41% — revenue dropping faster signals lower-value sales / heavier discounting.
- Discounts are uniform (~0.6%) across all card types — not a cause of the decline.
- **Shipping time tripled** — ~57 to ~174 days — a critical fulfilment failure tracking every other decline.

Recommendation

The decline is operational as much as commercial: the shipping-delay spike aligns tightly with falling satisfaction, orders and revenue. Priorities — fix Q3–Q4 fulfilment, protect the concentrated top-state customer base, and monitor per-order value.

Self-authored SQL analysis (10 queries). Course brief and dataset not redistributed.
